

1a. The registration office user would need access to the course info, prerequisite info, section info, the student's name/student number and Major. They probably wouldn't need access to the student's grade report.

1b. The admissions office user would need access to the student's grade report, the student's info, and prerequisites. If they are helping the student register for classes they would also need access to the courses and sections offered by the school.

1c. The Transcripts office user would need access to the student's grade report, and the student's info. If they are not helping the student register for classes, then they would have no need for section, prerequisite, and course info.

2. Some examples of data constraints would be that grades need to be restricted to a few options, namely A/B/C/D/F/WC/WF, etc. (+/- modifiers on each would also be useful, but depending on the university policies) Each Prerequisite Course_number must match up with a section's Course_number and Course's Course_number (ideally one that the university offers)

3. My experience working with databases comes from my time in the military. I was a database management administrator, and would routinely input and audit flight information (USAF) and pilot training, etc. Funnily enough I saw all the problems that the ancient databases we used had and decided to go to college for CS because I felt like I had maxed out all my skills in using MS Excel Visual Basic/macro programming and all that. Now I'm here writing about databases again :)
